Preface

In late 1976, a study to produce a wave climate for U. S. coastal waters was initiated at the U. S. Army Engineer Waterways Experiment Station (WES). This Wave Information Study (WIS) was authorized by the Office, Chief of Engineers, U. S. Army, as a part of the Field Data Collection Program which is managed by the U. S. Army Coastal Engineering Research Center. The U. S. Army Engineer Division, South Atlantic, and the U. S. Army Engineer Division, New England, also authorized funds during the initial year of this study (FY 1978) to expedite execution of the Atlantic coast portion of this program.

This report, the seventh in a series, presents the water-level climate, in a statistical sense, for the U. S. Atlantic coast and is intended for use in conjunction with the hindcast wave statistics generated for this same geographical area. The study was conducted in the Hydraulics Laboratory under the direction of Mr. H. B. Simmons, Chief of the Hydraulics Laboratory, Dr. R. W. Whalin, Chief of the Wave Dynamics Division, Mr. C. E. Chatham, Jr., Chief of the Wave Processes Branch, and Dr. D. T. Resio, Research Physical Scientist and Project Manager. This report was prepared by Mr. B. A. Ebersole.

Commanders and Directors of WES during the conduct of the study and the preparation and publication of this report were COL Nelson P. Conover, CE, and COL Tilford C. Creel, CE. Technical Director was Mr. F. R. Brown.

ATLANTIC COAST WATER-LEVEL CLIMATE

Introduction

1. The propagation of water waves into regions of shallow depths results in transformations and attenuations that are very much a function of water depth. During storms, the local wave growth is, of course, related to the wind field. This wind field, in turn, can cause changes in local water level that may be of great significance if the wind speed is high and the water depths are shallow. As a result of the correlations between wind and water level, there is a corresponding interdependence between wave height and water level. Consequently, at a given coastal site, the probability of any wave height must account for the probability distribution of both wave parameters and total water level.

2. The aim of this phase of the Wave Information Study (WIS) is the development of a statistical model containing probabilistic estimates of the coastal water-level climate as well as information concerning its spatial and temporal variation. At present, work is being confined to the Atlantic coast since the bulk of the wind, pressure, and wave information has been computed for this region. The following aspects of the water-level climate will be included in the formulation of the model: (a) long-term trends in the mean sea level and fluctuations about the general trends, (b) seasonal as well as yearly estimated probability density functions (PDF's), for the water level and its constituent components, which are derived from histograms of hourly values, (c) an analysis of the likelihood of occurrence of extreme water levels, and (d) a quantification of the duration of the water level above certain elevations for both expected and extreme conditions.

3. Eventually, certain aspects of the statistical model for water levels will be incorporated into the statistical model for waves to compute joint wave height-water level statistics. These statistics, as well as the water-level information as a separate entity in itself, will be an integral part of the Seastate Engineering Analysis System (SEAS)

which will make all aspects of the WIS available to Corps of Engineer District offices in an interactive way.

Establishment of a Reference Datum

4. The sea surface elevation varies in both space and time due primarily to the combined effects of the following physical processes: (a) long-term tectonic changes in the earth's crust resulting in either submergence or emergence of the land producing a relative rise or fall in the measured water level, (b) long-term changes in the volume of the earth's oceans due to polar ice melt and variations in precipitation and evaporation, (c) gravitational forces exerted by the masses of the sun and moon on the earth's water bodies, which in the course of this study will be referred to as the astronomical tide, or just tide, (d) forcing due to wind and gradients in atmospheric pressure as a result of meteorological events which will be referred to as storm surge, or surge, (e) geostrophic adjustments of water levels across currents, and (f) wind-generated ocean waves. Excluding the fluctuations due to waves, the majority of variation in the water surface is due to effects (c), (d), and (e), which are the primary components of the water level treated in this study.

5. Vertical variations in water level are usually measured relative to some arbitrary datum. In this study that reference point is chosen to be yearly mean sea level, a tidal datum. Yearly mean sea level is the computed average, over a period of 1 year, of all the fluctuations in water level relative to some zero point on a measurement device. This zero point is then referenced to other inland benchmarks creating a "fixed" system from which changes in the sea surface can be confidently measured. Yearly mean sea level, despite the fact that it does change due to effects (a) and (b) above, seems to be the best choice of a base datum, since relative to the time scales associated with the primary variations in water level it is essentially constant. Figures in Appendix A, pages A1-A20, illustrate, for selected east coast tide stations along the entire Atlantic Coast, the trends in yearly mean sea level as well as the

fluctuations of the monthly mean sea level about the general trends.

6. Notice that for the northernmost stations the magnitude of the monthly variability is fairly small compared with that for locations in the central and southern portions. This is due to the fact that the meteorologic effects of the extratropical, or "winter," storms are less in this region than in the middle latitudes and the effect of the tropical storms is nearly nonexistent. Along the central U. S. coast, where the effects of the extratropical storms predominate and the influence of tropical storms increases, the magnitude of the variability about yearly mean sea level also increases.

7. The large variability of the monthly means about the yearly mean is another reason why the more predictable yearly mean sea level is chosen as the reference datum. If the monthly mean is used, the variability of a substantial meteorologically induced storm surge about the datum is lessened, masking the true magnitude of that particular surge event when comparing events separated by time spans on the order of months and years.

8. A good description and documentation of the characteristics of mean sea level along the entire United States coastline can be found in Hicks and Crosby (1974) and Hicks (1978). Figure 1 is taken from the latter publication and shows the computed trend in yearly mean sea level and the variability about the trends for selected National Ocean Survey (NOS) tidal recording stations. Notice in both the plots and the table that the entire east coast, in the last 60 years, has undergone and is continuing to experience a relative rise in sea level. This kind of information, although not dealt with in much detail here, may be important in determining design criteria for long-life coastal structures as well as in explaining and predicting long-term coastal morphological changes such as barrier island migration.

Generation of the Statistical Model Data Base

9. As stated earlier, the principal causes of water-level variation about the yearly mean sea level datum are the astronomical tide and

Figure 1. Trends and variability of yearly mean sea level along the U. S. coast (Hicks 1978)

the storm surge. It is assumed in this study that these two components are physically independent. This assumption is valid in regions of the open coast where the water depths increase fairly rapidly offshore and provided the coastline does not form semienclosed embayments. In locations where these conditions are not met, interactions between the two components become increasingly significant and the assumption becomes less valid. Unfortunately, most of the tide recording stations are located in sheltered, shallow areas to protect them from the open-coast environment. However, in the course of performing the data analysis, unless the meteorologically induced surge was of a large magnitude and of a relatively short duration or if the tide range at a particular station was large, the results seem to indicate that the expression below is acceptable

$$WL = SS + T \quad (1)$$

where

WL = total water level

SS = storm surge

T = astronomical tide

In the first of the above exceptions, the effect of a large, "fast" surge such as a hurricane is to alter the propagation speed of the tide causing a phase lag between any predicted tide and the true water level. The second exception, which is similar to the first but with a different cause, also arises from the method used to extract the storm surge by subtracting the predicted tide from the measured water level. If the tide range is large, any phase error whatsoever between the predicted tide and the measured water level results in a surge component that oscillates with the frequency of the predicted tide. If the amplitude of the oscillation is small, this effect can be neglected; but if the amplitude is large, the effect is significant and is corrected through the use of a numerical filter.

10. Somewhat related to the assumption of physical independence is the concept of statistical independence. A fundamental aspect of the

statistical model formulation is the assumption that the tide and the surge are statistically independent events. In other words, the probability of occurrence of one event (say, some surge level) is unaffected by the fact that a particular tide elevation exists.

11. The raw data used in the study are comprised of historical water-level records from 20 NOS tidal reference stations. Figure 2 shows the locations of these stations also listed in Table 1. In addition, the table shows the approximate dates for which water-level data are available.

12. Data are preprocessed in the following ways in order to get them into a form that can be analyzed. Data are scanned for periods during which there are missing data, bad data in terms of tape errors, or times when tropical storms may have influenced the measurements. The dates for which tropical storms may have influenced the Atlantic coast in the locations under study were obtained from Tropical Cyclones of the North Atlantic, 1871-1977, issued by the National Oceanic and Atmospheric Administration. It is important to note at this point that the quantity storm surge, as defined in this report, includes all meteorologically induced water-level anomalies except those due to tropical storms.

13. Analyzing one month at a time, the hourly values of water-level data are read from magnetic tape. An appropriate yearly mean sea level (from NOS tabulated values) is subtracted from all the values to reference the data to the base datum, and the predicted astronomical tide is subtracted from the water levels, leaving a residual which is called the storm surge in accordance with Equation 1. The storm surge time series then undergoes additional editing and is finally added to the astronomical tide to re-form the time series for total water level. These three time series become the processed data base for use in the statistical model formulation. The prediction of the tide as well as the editing of the storm surge time series is discussed in more detail below.

14. Due to variations in the orbits of the moon and earth about the sun, the gravitational forcing of the sun and moon on the earth's

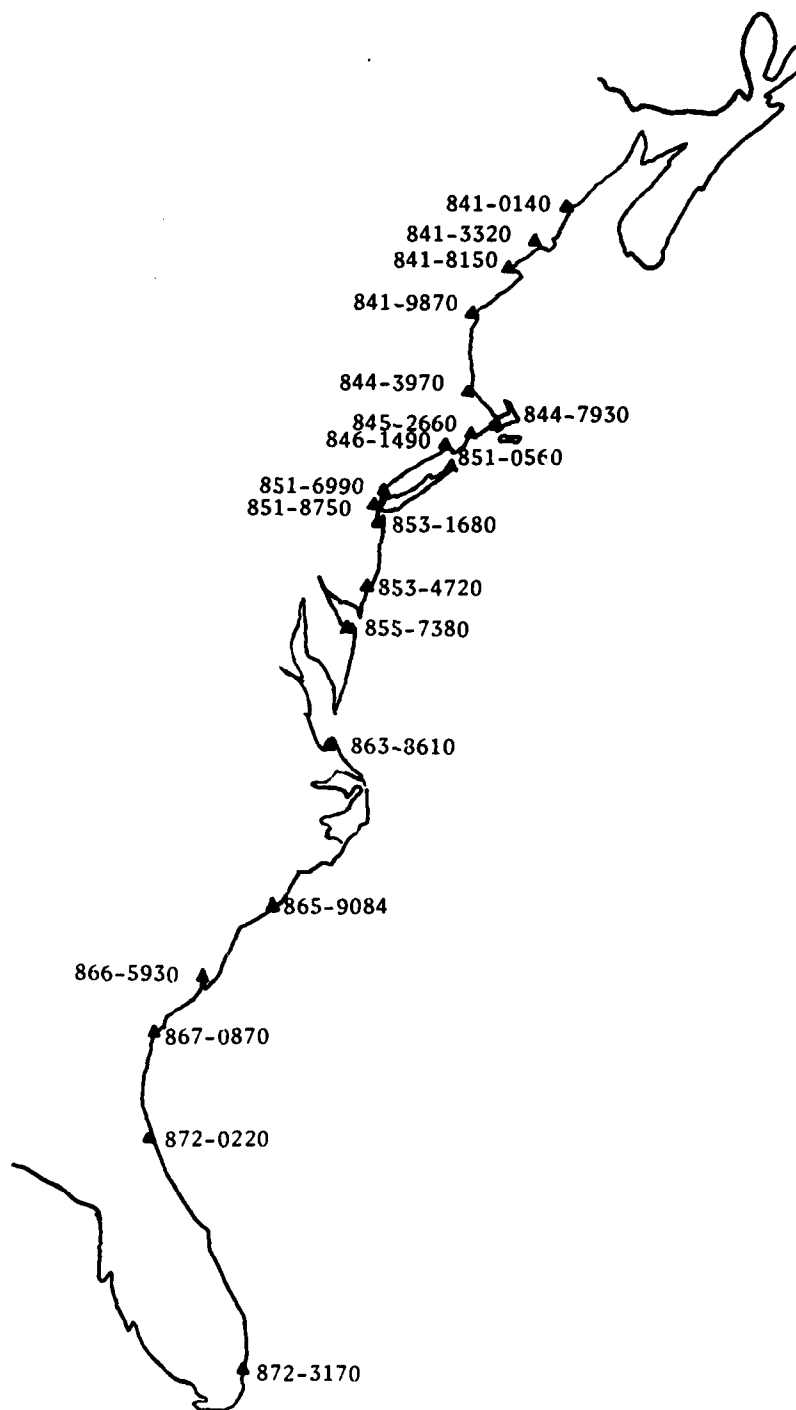

Figure 2. Geographical locations of east coast tidal reference stations investigated in the study

water bodies oscillates in a complex yet periodic fashion with components at many different frequencies combining to form the total effect. For practical purposes the astronomical tide can be represented as a finite sum of harmonic forcing functions,

$$\eta(t) = \eta_o + \sum_{i=1}^N a_i \cos (\sigma_i t - \epsilon_i) \quad (2)$$

where

$\eta(t)$ = tide elevation at any time t

η_o = elevation of some arbitrary datum (in this instance, yearly mean sea level) relative to some "fixed" reference point

N = total number of components considered with periods of oscillation less than 1 year (given in Schureman 1958)

a_i = amplitude of the individual components

σ_i = frequency of the i^{th} component

ϵ_i = phase of the individual components

15. Those forcing components with periods of oscillation greater than 1 year are taken into account by representing all of the constituent amplitudes and phases as the product of a mean amplitude and phase and a scale factor representing the oscillation about each mean. Therefore, Equation 2 can be rewritten as,

$$\eta_{ys}(t) = \eta_o + \sum_{i=1}^N f_{iy} A_{is} \cos (\sigma_i t - v_{iy} - K_{is}) \quad (3)$$

where

$\eta_{ys}(t)$ = tide height at any location s during year y

f_{iy} = modification of the constituent mean amplitudes during year y

A_{is} = mean amplitude of the i^{th} constituent at location s

v_{iy} = modification of the constituent phases during year y

K_{is} = phase of the i^{th} constituent at location s

The longest element of periodicity reflected in the perturbation of these mean quantities is about 19 years. It should also be noted that the amplitude modification factors f_{iy} and the phase modification factors v_{iy} are only functions of time and are not dependent on location, whereas the mean quantities A_{is} and K_{is} are constant with time but do vary with location.

16. The combined parameters $f_{iy}A_{is}$ and $(v_{iy} + K_{is})$ are determined through an analysis of the observed tidal record at some location for some length of time, usually 369 days. The quantities f_{iy} and v_{iy} , which are also given in Schureman (1958), are then used to find the A_{is} 's and K_{is} 's. These last two "station constants," as they are called, can be obtained from NOS.

17. In Equation 3, the time t can be represented by

$$t = n\Delta t \qquad n = 1, 2, 3, 4, \dots \qquad (4)$$

By choosing Δt as 1 hr, successive values of the astronomical tide can be predicted on an hourly basis which can then be subtracted from the total water level to yield a time series of storm surge values.

18. The storm surge values are edited in one and possibly both of the following ways. All of them are first checked for discontinuities which take the form of spikes due to errors in recording the hourly water level. These spikes are smoothed using simple averaging across the discontinuity. These kinds of errors are rare in comparison to the total number of hourly values examined; however, they should be corrected in order to obtain the most accurate representation of the storm surge time series.

19. The second type of editing is done on the storm surge records of stations with large tidal ranges or pronounced shallow-water effects. As mentioned earlier, if the phase of the predicted tide is slightly different from that of the actual tide, the computed storm surge exhibits the periodicity of the predicted astronomical tide. For stations with

smaller tide ranges the amplitude of this oscillating anomaly is negligible, but for those with large tide ranges the effect must be accounted for if meaningful values of surge are to be obtained.

20. A simple yet effective way to remove this anomaly is to employ a single component Fourier filter with the component frequency matching that of the tidal constituent with the largest amplitude. Figures 3-6 show the effect of the filter on the storm surge at Charleston, S. C., and Seavey Island, Maine, during periods of both low and high surge. The same filter was also applied to the storm surge time series at Boston, Mass.; Eastport, Bar Harbor, and Portland, Maine; Southport, N. C.; Atlantic City, N. J.; Fort Pulaski, Ga.; and Mayport and Miami Beach, Fla. Since the storm surge series alone, and summed with the tide to produce the water-level series, are an integral part of the statistical model formulation, it is important that they be as accurate as possible.

Statistical Analysis

21. Up to this point the procedure used in generating the statistical model data base, the three time series of hourly values, has been presented. These data are useful in obtaining the following information at each site analyzed: (a) a probabilistic estimate of the magnitude of expected water levels in both a seasonal and yearly sense, via estimated PDF's and cumulative distribution functions (CDF's) derived from histograms of hourly values, (b) durations of expected water levels above certain values, and (c) seasonal as well as yearly variation in extreme storm surges. The extremal information presented here will supplement numerically simulated storm surge data in the formulation of extreme statistics for both tropical and extratropical storms. This formulation as well as the linking of the tidal statistics with the extreme surge statistics in order to evaluate extreme total water levels will be presented in a later report.

22. It must be remembered that the recorded data and the statistical results derived from them are site-specific; i.e., there is available

Figure 3. Effect of the Fourier numerical filter on the storm surge time series at Charleston, S. C., 6-7 May 1945

Figure 4. Effect of the Fourier numerical filter on the storm surge time series at Charleston, S. C., 1-3 Nov 1947

Figure 5. Effect of the Fourier numerical filter on the storm surge time series at Seavey Island, Me., 12-13 Sep 1946

Figure 6. Effect of the Fourier numerical filter on the storm surge time series at Seavey Island, Me., 27-30 Nov 1945

information at only a few widely dispersed points along the coast. Since this information is also desired at the same spatial scale for which wave information from Phase III is available, reasonable methods will be suggested for extrapolation of results to data sparse areas. These methods are crude, yet represent a possible solution to the extrapolation problem until more data become available.

Expected water-level climate

23. The time series of hourly values of water level, storm surge, and astronomical tide are analyzed 1 month at a time with the following information available for each month: (a) a listing of the tide and the surge, nonfiltered and filtered if applicable, (b) output onto magnetic tape of the storm surge and total water-level time series for use in the duration analysis, (c) breakdown of the hourly values into histograms using the parameters shown in Table 2 which are in the format:

Range in feet

Number of Intervals (Interval size in feet)

(d) computation of a monthly mean, standard deviation and a maximum and a minimum. The information from (c) and (d) is also written onto tape. The monthly histograms which are accumulated on both a month-by-month basis and a yearly basis, are used to compute estimated PDF's and CDF's. The statistical parameters mentioned in (d) are treated in much the same way in order to find their seasonal as well as yearly values.

24. Figures 7-9 illustrate the estimated yearly PDF's for all three water-level variables at Hampton Roads, Virginia, based on 0.1-ft histogram intervals. The bimodal shape of the tidal PDF is characteristic of all the east coast reference stations examined. The variance of this distribution is related to the mean tidal range. The PDF for the total water level has a similar shape but with reduced peaks and more spread tails; and again, this form is also common to the other stations. This particular distribution can also be derived by numerically

Figure 7. Estimated probability density function for astronomical tide at Hampton Roads, Va.

Figure 8. Estimated probability density function for total water level at Hampton Roads, Va.

Figure 9. Estimated probability density function for storm surge at Hampton Roads, Va.

convolving the tidal PDF with the storm surge PDF.

25. Notice the similarity in shape between the storm surge distribution and a normal distribution. Despite its appearance, the unimodal storm surge PDF is not Gaussian but instead has a positive skewness. This general shape is characteristic of all those locations analyzed. Also note how the derived distribution using 20 years of data corresponds to that using 42 years of data. The negligible differences illustrate the stationariness of the statistics reflected by the storm surge PDF in this time frame.

26. In working with the data, it was found that about 10 years of data were necessary to formulate reasonably stationary yearly statistics. However in this work, about 20 years of data, or as much as was available, was used for all the stations since this length of time corresponds to the largest periodicity of the tidal cycle--about 19 years. The use of about 19 years of astronomical tide data assures us of a relatively stationary tidal PDF. The annual and semiannual variations in the astronomical tide are not included in the statistics presented for Eastport, Bar Harbor, Seavey Island, Montauk Point, and Southport.

27. This probability density and cumulative distribution information for all the stations is presented in tabular form in the tables shown in Appendix B, pages B1-B260. The stations are arranged, as in Table 1, in descending order as you move down the Atlantic coast. This order will be used in all subsequent graphics. Each station has 13 pages of this kind of information, the first being the "average" yearly statistics for the three variables, tide, surge, and total water level. The next 12 pages for each station contain the same information on a month by month basis. The approximate means and standard deviations, computed using the interval center values and the number of occurrences, are also included in these tables. It is important to emphasize that care must be exercised in using the right-hand portions (large positive elevations) of these PDF's and CDF's. A detailed extreme value analysis for these larger values will be the subject of a subsequent report.

28. Another statistic of concern, but not often investigated, is the duration of water levels above certain elevations. Figures in

Appendix C, pages C1-C40, show the average and maximum durations above certain levels, once those levels have been exceeded. There are two plots for each station, one for the total water level and one for the storm surge. Three important points should be made about this series of figures. First, these statistics were derived using hourly time series with record lengths from only 2 to 5 years (not the total record length of data analyzed) due to computer storage limitations. This created end effects at the left-hand portions of the curves, which can be tolerated since the majority of interest lies in the durations above larger values of the abscissa. Secondly, since the time series contained discontinuities due to bad or missing data, the computed maximum durations might be slightly conservative; however, the average durations are probably negligibly affected. Finally, as with the PDF and CFD information, caution must be used in interpreting results from the right-hand portions of the curves. On each plot the location is marked, beyond which is shaded, where fewer than 10 exceedances of a certain level were used to compute a maximum and an average. A separate duration analysis for extreme storm surges and total water levels (including the effects of the astronomical tide) will be presented in the subsequent report on extremes (paragraph 27).

29. The expected water-level climate at locations for which a sufficient quantity of data does not exist can be approximated in a statistical sense using the site-specific results from the tidal reference station data. Harris (1981) suggests a method for extrapolating the astronomical tide PDF's computed for these stations to data sparse areas. His method consists of "normalizing" the known PDF by its mean range and then multiplying it by the estimated mean range of some nearby location. The mean ranges for many locations along the coast are estimated and published by NOS in their yearly tide tables.

30. As seen in the PDF and CFD tables, the statistics for the storm surge vary in a fairly uniform fashion from station to station. A reasonable estimate for these statistics at some intermediate location can be obtained by using an average of the PDF's of two nearby sites or by using the results of the nearest station. This assumed form for the

storm surge distribution can then be numerically convolved with the estimated tidal distribution in order to arrive at acceptable statistics for the expected total water-level climate.

Extreme water-level climate

31. As mentioned before, work is being done on a report that will contain statistics on the magnitudes and durations of large storm surges due to both tropical and extratropical storms, which in turn will be incorporated with the astronomical tide results presented here to form extreme total water-level statistics. All of this information will be available on a spatial scale that is compatible to that of the near-shore wave statistics.

32. Notwithstanding, the data recorded at the tidal reference stations are of sufficient length that they can be useful in obtaining information on extreme meteorologically induced surges. These data and subsequent statistically derived results can then be used as a check on and a supplement to those derived from the numerically simulated data. In this report only the quantity storm surge will be dealt with in terms of extremes. Problems in determining total water-level extremes will be discussed later in this section.

33. In this study the extratropical storm surge extremes will be incorporated into a "typical" extreme event theory under the assumption that the data follow this particular probability law. Using this theory, different analyses will be done to illustrate certain applications of extreme event data. In many instances the data support the assumed theory quite well, yet in others the fit is not very good. This type of procedure is that which is most commonly used in dealing with extreme water levels and storm surges. At the end of this section questions are raised as to whether or not this is the best possible approach.

34. The data used for our assumed theory are the monthly maxima of storm surge measured at each tidal reference station. The largest of these values are computed by hand using Equation 1. Reiterating, any increase in the water level due to a substantial meteorological effect alters the propagation speed of the astronomical tide, producing phase errors between the actual and predicted tide and creating the

oscillating effect in the surge time series. The predicted astronomical tide time series are shifted in time to obtain a more realistic representation of the actual storm surge.

35. These data values are then used as input into the theory with the following underlying assumption: the maxima, each being the largest of between 400 and 744 hourly values during the month, follow a double exponential or Gumbel type distribution given by,

$$P(x \leq X) = \exp \{-\exp [-\alpha (X - \mu)]\} \quad (5)$$

or alternatively,

$$X = \mu - \frac{1}{\alpha} \ln (-\ln P) \quad (6)$$

where

P = probability that the storm maximum x is less than or equal to some value X

μ and α = statistical parameters which characterize the particular distribution of monthly maxima

It is also assumed that the yearly maxima, the largest of the 12 monthly maxima during a given year, follow the same distribution. The parameters α and μ are found by fitting a straight line to points whose ordinate is the maxima values themselves, and the abscissa is a reduced variate defined by

$$y = \frac{x - \mu}{\alpha} \quad (7)$$

An average least-squares fit, in terms of both the abscissa and ordinate, is used to determine the "best" straight line. For a complete description of this method, see Gumbel (1954).

36. Data for the monthly extremes as well as the yearly extremes are presented in Appendix D, pages D1-D140. Each station has 13 figures, 1 for the yearly maxima and 12 for the monthly extrema. The frequency of

occurrence P is plotted on the abscissa in a double logarithmic fashion and the surge maxima are plotted on the ordinate in a linear scale.

37. The frequency P , used in plotting the points, is found by ranking the surge extremes from smallest to largest and then dividing the rank of each by the total number of maxima examined plus one, $N + 1$,

$$P = \frac{M}{N + 1} \quad (8)$$

where M is the rank from below.

38. If the double exponential theory does indeed hold, the maxima values should plot as a straight line using the axis configuration in the plots. The return period T , given simply by

$$T = \frac{1}{1 - P} \quad (9)$$

is plotted along the top. The return period is the time in years during which a particular value of the storm surge can be expected to be surpassed during some time frame, whether it be a year or a particular month.

39. The tables shown in Appendix E, pages E1-E10, contain the α , μ pairs computed for the year and for each month as well as the number of extremes used to compute them. The μ value gives an indication of the average magnitude of the extreme values, i.e. the most expected extreme where larger μ indicates larger values. The α parameter is a measure of the range of extremes encountered with lower α values corresponding to more variance in the extremes. In addition, the 2-, 5-, 10-, 20-, and 50-year return period events are computed using the appropriate α , μ pair and letting P be equal to 0.50, 0.80, 0.90, 0.95, and 0.98, respectively, in Equation 6.

40. If we assume that the extremes for each month come from different populations and that the maximum events from successive months are statistically independent, the probability that during the year the surge x is less than or equal to X can be expressed as the product

of the 12 monthly exceedance probabilities,

$$P(x \leq X) = \prod_{i=1}^{12} \exp \{-\exp [-\alpha_i (X - \mu_i)]\} \quad (10)$$

The last line in each of the tables gives the same return period estimates using this equation. This is just an alternative approach to that using yearly extremes.

41. The frequencies of occurrence and corresponding return periods derived from the Gumbel theory are not absolute, deterministic quantities. As with other probability theories there are confidence bands associated with the line defined by any α , μ pair. These confidence bands, or control curves as they are called here, are useful in (a) determining the risk associated with assuming a particular frequency of occurrence (or return period), (b) determining whether or not the theory is acceptable, and (c) making decisions on which, if any, points constitute "outliers" within the data set. The following is a brief explanation taken from Gumbel (1954) on the computation of these control curves. A sample problem illustrating the computations is also presented.

42. It is assumed that for any particular occurrence frequency in the range 0.15 to 0.85 the corresponding storm surge is asymptotically normally distributed about some mean and with some variance. This mean surge value is that predicted by Equation 6 for a specified α , μ pair. The variance is expressed in terms of standard errors, Δx , which are added to and subtracted from the mean value, thus forming the control curves. Accordingly, there is a probability of 0.6827, corresponding to one standard deviation, that the actual surge value for a particular exceedance frequency lies within one standard error on either side of the mean. If twice this standard error is used, the probability that the surge lies within this standard error increases to 0.9545. The ends of these control intervals at each frequency are connected, forming control curves. Knowing the parameter α and the number of extremes used in its computation, N , the standard errors corresponding to the discrete frequencies of exceedance, P , can be computed using Table 3, where

$$Q = \alpha\sqrt{N} \quad (11)$$

43. The control curves are also extended to the largest (L) and the second largest (L-1) theoretically predicted surge values. The standard errors, within which there is a 0.6827 chance that the surge value corresponding to a particular frequency will lie, are given by

$$\Delta X_L = \pm \frac{1.14071}{\alpha} \quad (12)$$

and

$$\Delta X_{L-1} = \pm \frac{0.75409}{\alpha} \quad (13)$$

for the largest and next largest values, respectively. For a probability of 0.9545 the control intervals become

$$\Delta X_L = \pm \frac{3.06685}{\alpha} \quad (14)$$

and

$$\Delta X_{L-1} = \pm \frac{1.78196}{\alpha} \quad (15)$$

These control intervals are again added to and subtracted from the theoretical predictions, the ends of which are connected to the control curves at the lower frequencies. To extend the control curve beyond the largest value measured, the standard error associated with this value is added and subtracted from the predicted line. It must be remembered that as with any theory, the control curves, or confidence bands, are an integral part. Along with the theoretical line defined by any α , μ pair they suggest the most probable surge heights associated with a particular frequency of occurrence, or return period. This is actually a statement of the risk involved in selecting a certain probability of exceedance and its corresponding surge levels. The procedure for constructing control curves is illustrated in Figures 10 and 11.

Figure 10. Graphical illustration of the application of the "Gumbel" extreme value theory

44. A typical treatment of extremes has been applied to both monthly and yearly storm surge maxima, in which a theoretical model has been postulated and the data are assumed to follow the theory. In this way some information is obtained about the variation in the statistics of extreme surge heights along the Atlantic coast. By using this particular method of analysis we characterize a storm event by a single scalar, the peak surge.

45. However, many factors combine to determine the magnitude of this scalar quantity such as wind speed and direction, storm track, storm duration, atmospheric pressure gradients, and the orientation of

Figure 11. Computations required for the application of the Gumbel extreme value theory

the coastline relative to the storm geometry. A better formulation of the extremal problem might be to evaluate the surge statistics in terms of statistics of the above storm characteristics. In this way the dynamics of storm generation are better related to the storm surge and insight is gained into the problem of mixing populations of different kinds of storms, which is inherent in assuming that all the data fit some theoretical model. This type of approach is being investigated and any results from it are expected to be presented in the separate extreme event report.

46. An interesting example that illustrates this point is the following. For the yearly extreme storm surge analysis at locations within the New York Bight area, the November 1950 storm produced a peak surge that appears to be an "outlier" in the plot. One might assume, therefore, that it was an extremely rare event that just happened to occur during the period for which the data were recorded. However, upon inspecting the extremal statistics for the month of November at these same locations, the data points appear to lie on either of two fairly straight lines, each with a different slope. The 1950 storm, among others, lies on the upper line. In this perspective, that particular event does not appear to be an outlier, but rather is included in one of two different kinds of storms distinguished apart by some storm characteristic or group of characteristics. It is obvious how the treatment of this one storm can influence the anticipated return period associated with this magnitude of storm surge.

47. The subject of extreme total water levels (the concurrence of large storm surges and astronomical tides) to this point has been left untouched. A few unanswered questions are involved in the generation of extremal statistics for water levels. The following discussion will illustrate a common method for analyzing these extremes, problems associated with this method, and possible alternatives to the approach.

48. A common practice in the analysis of water-level extremes is to treat them in the same way as the storm surge, by assuming that a particular data set fits a postulated theoretical model. Figure 12 shows a plot of the yearly total water-level extremes at Sandy Hook, N. J.,

Figure 12. Gumbel theory applied to yearly extreme water-level data at Sandy Hook, N. J.

assuming that the Gumbel theory holds. One might be fairly confident in using the computed best fit line along with the control curves to extrapolate to larger values associated with longer return periods. Once again, however, there is evidence of two or even more different regions represented by the data, each with a different characteristic slope. As stated earlier, this might indicate the presence of difference populations of events that are being analyzed together.

49. Table 4 is a breakdown of each of these extreme points into its surge and tidal components along with additional information about these two variables during the event that produced the extreme water

level. Contained in the table are the following: (a) the year and month for each data point; (b) the water-level value (WL), the surge (SS), and tidal (T) component; (c) the maximum (T_{\max}) and minimum (T_{\min}) tides surrounding the time of peak water level; (d) the maximum surge (SS_{\max}) during the particular storm event and also the magnitude of the tide coincident in time with this peak surge ($T_{SS_{\max}}$); and (e) the duration(s), in hours, for which the storm surge during the event remained above the values listed (commas separate different times during the same event for which a particular level was surpassed).

50. First, notice that the extreme water levels occur primarily in the months October through March. This is to be expected since during this winter season the largest extratropical storms that affect this area of the coast are generated. Secondly, note the similarity between the tidal component of the extreme water levels (T) and the high tide values (T_{\max}). All the extreme water levels occurred at or near high tide; however, the data also seem to be comprised of three groups of surge-high tide combinations: (a) large "spring" tides and average or negligible storm surges, (b) fairly substantial surges that are about of the same magnitude as the high tide, and (c) surge components that are much larger than the high tides and produce the largest extreme water-level conditions. These are the points with which we are most concerned when analyzing extreme water levels.

51. The question can then be raised whether or not it is correct to plot together these three classes of points that arise due to different meteorological/climatological conditions and then extrapolate to find the water levels associated with longer return periods. Figure 12 shows evidence that the lower values of the extreme water levels have a particular slope which is dictated by the population of yearly high tides (generally 3.8 to 4.0 ft) yet the higher values indeed do tend to lie along a different slope. Therefore the answer to the question raised above is probably no.

52. An alternative approach must be found in which the events that produce the largest values of total water-level are analyzed separately. This involves the numerical convolution of extremal storm

surge statistics with appropriate seasonal tidal statistics. In Table 4, notice the peak surges associated with each event (SS_{\max}), the concurrent tidal component ($T_{SS_{\max}}$), and the tide range reflected by T_{\max} and T_{\min} . It appears from the data that the peak surge can occur at any time during the tidal cycle. However, this is probably subject to an additional parameter, the duration of the event, and the surges produced by it. For example, if a storm generates a fairly constant surge for more than 12 hr, the peak surge will occur at low tide due to hydrodynamic effects associated with the decrease in total water level. The peak total water level will still occur at high tide. If, on the other hand, the storm surge varies significantly during the 12 hr, the peak surge can occur at any time during the tidal cycle. As illustrated by the data the peak water level will probably occur at high tide with a value of the storm surge that is less than the peak value. Again, this is really constrained by the variation in the magnitude of the surge. During this kind of event, the possibility always exists for the peak surge to occur during high tide, thereby producing an extremely high water level.

53. The extreme water-level analysis then depends on (a) the magnitudes and durations of large storm-induced surges, and (b) the tidal conditions that can be expected to exist during these storm events. By knowing the extreme surge magnitude statistics and keeping the statistics of surge durations for different magnitudes in mind, one could convolve all or portions of the surge statistics with all or parts of the tidal statistics. For example, on the average, the lower values of storm surge during an event can be expected to be surpassed for at least a tidal cycle. Therefore, their statistics should be convolved with the statistics of higher tides only, in order to produce expected extreme water levels. In the case of the large surges, whose durations are only on the order of 1 to 2 hr, their statistics should be convolved with statistics that reflect all or a majority of the tidal cycle.

54. The continuing effort in the determination of extreme water levels is taking this direction. By first defining the statistics of extreme storm surges in terms of probabilities of meteorologic and

climatologic dynamics and then defining statistics of surge durations, many of the questions involving the estimation of extreme water levels can hopefully be answered.

[The page contains several horizontal bands of dense, illegible markings or noise.]

[Illegible handwritten notes at the bottom left corner]

1. The first part of the document is a list of names and addresses, which are arranged in a columnar format. The names are written in a cursive script, and the addresses are written in a more formal, printed style. The list includes names such as "John Doe", "Jane Smith", and "Robert Johnson", along with their respective addresses.

2. The second part of the document is a series of numbered entries, each followed by a description of a property or item. The numbers are written in a cursive script, and the descriptions are written in a more formal, printed style. The entries are numbered from 1 to 10, and each entry describes a different property or item.

3. The third part of the document is a series of numbered entries, each followed by a description of a property or item. The numbers are written in a cursive script, and the descriptions are written in a more formal, printed style. The entries are numbered from 1 to 10, and each entry describes a different property or item.

4. The fourth part of the document is a series of numbered entries, each followed by a description of a property or item. The numbers are written in a cursive script, and the descriptions are written in a more formal, printed style. The entries are numbered from 1 to 10, and each entry describes a different property or item.

5. The fifth part of the document is a series of numbered entries, each followed by a description of a property or item. The numbers are written in a cursive script, and the descriptions are written in a more formal, printed style. The entries are numbered from 1 to 10, and each entry describes a different property or item.

1. The first part of the document is a list of names and addresses, which are arranged in a columnar format. The names are written in a cursive script, and the addresses are written in a more formal, printed style. The list includes names such as "John Doe", "Jane Smith", and "Robert Johnson", along with their respective addresses.

2. The second part of the document is a series of numbered paragraphs, each containing a different piece of information. The paragraphs are numbered from 1 to 10, and each paragraph is preceded by a small, decorative symbol. The text in the paragraphs is written in a cursive script, and the symbols are arranged in a columnar format.

3. The third part of the document is a series of lines of text, each containing a different piece of information. The lines are arranged in a columnar format, and each line is preceded by a small, decorative symbol. The text in the lines is written in a cursive script, and the symbols are arranged in a columnar format.

4. The fourth part of the document is a series of lines of text, each containing a different piece of information. The lines are arranged in a columnar format, and each line is preceded by a small, decorative symbol. The text in the lines is written in a cursive script, and the symbols are arranged in a columnar format.

5. The fifth part of the document is a series of lines of text, each containing a different piece of information. The lines are arranged in a columnar format, and each line is preceded by a small, decorative symbol. The text in the lines is written in a cursive script, and the symbols are arranged in a columnar format.

In accordance with letter from DAEN-RDC, DAEN-ASI dated 22 July 1977, Subject: Facsimile Catalog Cards for Laboratory Technical Publications, a facsimile catalog card in Library of Congress MARC format is reproduced below.

Ebersole, Bruce A.

Atlantic coast water-level climate / by Bruce A. Ebersole (Hydraulics Laboratory, U.S. Army Engineer Waterways Experiment Station). -- Vicksburg, Miss. : The Station ; Springfield, Va. : available from NTIS, 1982.

495 p. in various pagings ; ill. ; 27 cm. -- (WIS report ; 7)

Cover title.

"April 1982."

"Prepared for Office, Chief of Engineers, U.S. Army."

"Wave Information Studies of U.S. Coastlines."

Bibliography: p. 35.

1. Atlantic Coast (United States). 2. Sea level.
3. Storm surges. 4. Water waves. I. United States. Army.
Corps of Engineers. Office of the Chief of Engineers.
